

## HistFactory Likelihood

### 1 The Likelihood Template

The parametrized probability density function constructed by the HistFactory is of a concrete form, but sufficiently flexible to describe many analyses based on template histograms. In general, the HistFactory produces probability density functions of the form

$$\mathcal{P}(n_m, m_i | \mu, \alpha_i) = \prod_{m \in \text{bins}} \text{Pois}(n_m | \nu_m) \cdot G(L_0 | L, \Delta_L) \prod_{i \in \text{Syst}}^5 N(m_i | \alpha_i, 1) \quad (1)$$

where  $m$  is an index over the bins of the template histograms,  $i$  is an index over systematic effects,  $\nu_m$  is the expected number of events in bin  $m$  given by

$$\nu_m = \sum_{j \in \text{Samp}} LF_j \eta_j(\boldsymbol{\alpha}) \sigma_{jm}(\boldsymbol{\alpha}), \quad (2)$$

where  $F_j$  is a product of unconstrained normalization factors for sample  $j$

$$F_j = \prod_{n \in \text{NormFact}_j} f_n \quad (3)$$

that typically include the parameter of interest (eg.  $\mu = \sigma/\sigma_{SM}$ ). The term  $\eta_j(\boldsymbol{\alpha})$  parametrizes relative changes in the overall normalization, and  $\sigma_{jm}(\boldsymbol{\alpha})$  contains the nominal normalization and parametrizes uncertainties in the shape of the distribution of the discriminating variable. Here  $j$  is an index of contributions from different processes with  $j = 1$  being the signal process. The nuisance parameters  $\alpha_i$  are associated to the source of the systematic effect (e.g. the muon momentum resolution uncertainty), while  $\eta_j(\boldsymbol{\alpha})$  and  $\sigma_{jm}(\boldsymbol{\alpha})$  represent the effect of that uncertainty. The  $\alpha_i$  are scaled so that  $\alpha_i = 0$  corresponds to the nominal expectation and  $\alpha_i = \pm 1$  correspond to the  $\pm 1\sigma$  variations of the source, thus  $N(\alpha_i)$  is the standard normal distribution. The effect of these variations about the nominal predictions  $\eta_j(0) = 1$  and  $\sigma_{jm}^0$  is quantified by dedicated studies that provide  $\eta_{ij}^\pm$  and  $\sigma_{ijm}^\pm$ , which are then used to form

$$\eta_j(\boldsymbol{\alpha}) = \prod_{i \in \text{Syst}} I(\alpha_i; \eta_{ij}^+, \eta_{ij}^-) \quad (4)$$

and

$$\sigma_{jm}(\boldsymbol{\alpha}) = \sigma_{jm}^0 \prod_{i \in \text{Syst}} I(\alpha_i; \sigma_{ijm}^+/\sigma_{jm}^0, \sigma_{ijm}^-/\sigma_{jm}^0) \quad (5)$$

with

$$I(\alpha; I^+, I^-) = \begin{cases} 1 + \alpha(I^+ - 1) & \text{if } \alpha > 0 \\ 1 & \text{if } \alpha = 0 \\ 1 - \alpha(I^- - 1) & \text{if } \alpha < 0 \end{cases} \quad (6)$$

enabling piece-wise linear interpolation in the case of asymmetric response to the source of systematic. In the next version of HistFactory, a quadratic interpolation will be available, and may become the default, as it avoids discontinuities in the second derivative that often confuse MINUIT and HESSE.

## 2 Implementation with HistFactory

Note, when using the `HistFactory` the production modes  $l$  and backgrounds  $j$  correspond to a single XML `Sample` element. The `HistoName` attribute inside each sample element specifies the histogram with the  $\sigma_{ijm}^0$ . The index  $j = 'J'$  is set by the `Name` attribute of the `Sample` element (eg. `<Sample Name='J'>`). Between the open `<Sample>` and close `</Sample>` one can add

- An `OverallSys` element where the `Name='I'` attribute identifies which  $\alpha_I$  is the source of the systematic and implies that the Gaussian constraint  $N(m_I|\alpha_I, 1)$  is present. The `High` attribute corresponds to  $\eta_{IJ}^+$ , eg when the source of the systematic is at  $+1\sigma$  and  $\alpha_I = 1$ . Similarly, the `Low` attribute corresponds to  $\eta_{IJ}^-$ , eg when the source of the systematic is at  $-1\sigma$  and  $\alpha_I = -1$ . The nominal value is  $\eta_{IJ}^0 = 1$  for the overall systematics. The distinction between the sign of the source  $\alpha$  and the effect  $\eta$  allows one to have anti-correlated systematics. The `HistFactory` is able to deal with asymmetric uncertainties as well, by using a piece-wise linear interpolation for the  $\alpha_I > 0$  and  $\alpha_I < 0$  regions.
- A `NormFactor` element is used to introduce an overall constant factor into the expected number of events. In the example below, the term  $\mu = \sigma/\sigma_{SM}$  corresponds to the line `<NormFactor Name='SigXsecOverSM'>`. In this case, the histograms were normalized to unity, so additional `NormFactor` elements were used to give the overall cross-sections  $\sigma_J$ .
- A `HistoSys` element is used to introduce shape systematics and the `HistoNameHigh` and `HistoNameLow` attributes have the variational histograms  $\sigma_{ijm}^+$  and  $\sigma_{ijm}^-$  corresponding to  $\alpha_i = +1$  and  $\alpha = -1$ , respectively.

Below is an example XML file for the electron channel.

```
<!DOCTYPE Channel SYSTEM 'HistFactorySchema.dtd'>

</Channel>

```

One can convert this Gaussian constraints into a Poisson/Gamma systematic by adding lines like

```
<ConstraintTerm Type="Gamma" RelativeUncertainty="0.1">JES</ConstraintTerm>
```

to the Measurement element. For example:

```

<Measurement Name="AllSYS" Lumi="35.2" LumiRelErr="0.11" BinLow="0" BinHigh="20" Mode="comb" ExportOnly="True">
  <POI>SigXsecOverSM</POI>
  <ParamSetting Const="True">NEle_AddOn,NEle_Atataui120,NEle_Atataui130,NEle_Others,
    NEle_SameSign,NEle_Ztautau,NEle_bbAtataui120,NEle_bbAtataui130,NMuo_AddOn,
    NMuo_Atataui120,NMuo_Atataui130,NMuo_Others,NMuo_SameSign,NMuo_Ztautau,NMuo_bbAtataui120,
    NMuo_bbAtataui130
  </ParamSetting>
  <ConstraintTerm Type="Gamma" RelativeUncertainty="0.1">JES</ConstraintTerm>
  <!--<ConstraintTerm Type="LogNormal" RelativeUncertainty="0.1">JES</ConstraintTerm-->
</Measurement>

```
