

Servers Reboot

Server

Execute the saveReboot.sh file.
Sometimes is necessary to reboot the Apache server.

Repository

- Execute <https://etics-repository.cern.ch:8443/repository/services/RepositoryService?method=startShutDown>: This will make the repository stop accepting new builds to its queue.
- Then check `/tmp/eticsRepositoryWSLog.log` and wait for this line to appear: "**SERVER SHUTDOWN - it is now possible to stop the Web Application container (i.e. Tomcat)**". This indicates that all the builds that were queued have finished and the statistics were serialized.
- Finally, execute the file `/root/safeRebootAfterShutdown.sh`, to restart Tomcat and clean its cache.
